In a liquid, molecules are "always colliding"; gases have a mean free path (distance b/w each collision)

Probability of collisions + No. of particles incident for a cross sectional area → gives survival equation

$l = \frac{1}{\pi \sigma^2 n}$

Effusion: gas leaks through a very small hole of diameter much smaller than the mean free path

$d \ll l$, molecules will undergo very few collisions

↳ this is where the "PV" term comes in idea of viscous stresses when forcing gas/liquid through orifice

Effusion is when the collision has already occurred & the gas just passes through.

Viscous stresses arise from net transport of momentum via gases moving at different speeds & colliding w/ other particles/molecules.
